## Introduction

- Genome Wide Association Studies (GWAS) are popular to identify causal variants for a trait.
- Besides the effect of sample size and markers density, relatively few studies have looked at the effects of population parameters and genetic models on the power and false positive rate of GWAS.
- Population parameters includes selection strength and effective population size, while genetic models are characterized by number and sizes of QTLs, heritability and non-additive genetic components.

### Aim

To investigate the effect of population parameters and genetic models on power, proportion of false positives and accuracy of estimated QTL effect sizes in GWAS

## Genetic Model

(Based on Duerk et al., 2020)

$$y = G_{a,k} \alpha_k + G_{d,k} \delta_k |\alpha_k| + G_{y,kl} \gamma_{kl} \sqrt{|\alpha_k \alpha_l|} + e$$

Symbol	Phenotype	Distribution Used:
$y$	Phenotype	$\alpha_k \sim N(0, 1)$
$G_{a,k}$	Additive Genotype Value; set at {0, 1, 2}	$\delta_k \sim N(0, \delta)$
$\alpha_k$	Additive Genetic Effect Size for locus $k$	$\gamma_{kl} \sim N(0, \gamma)$
$G_{d,k}$	Dominance Genotype Value; set at {0, 1, 0}	
$\delta_k$	Dominance Coefficient	
$G_{y,kl}$	Epistatic Genotype Value	
$\gamma_{kl}$	Epistatic Coefficient for loci $k$ and $l$	
$e$	Residual Value	

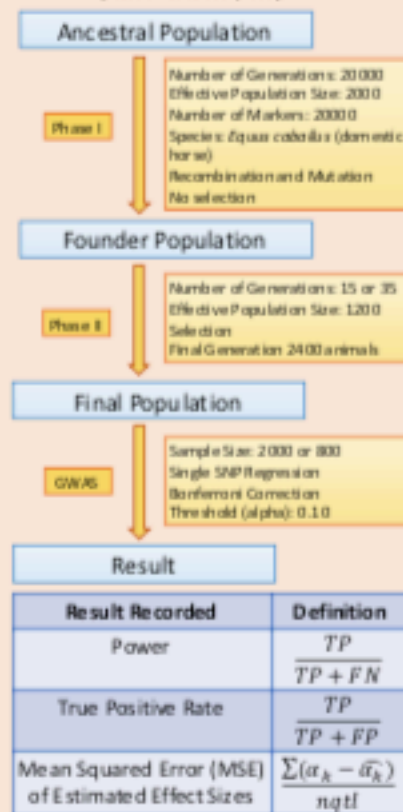

- $\alpha_k$  was then adjusted with narrow sense heritability
- Only  $\alpha_k \geq 0.1$  were included in result calculation.

## Parameter Tested

Parameter	Default Value	Alternative Value
Number of Generations	15	35
Proportion of Selected Males	0.5	0.2
Effective Population Size	1200	200
Narrow Sense Heritability	0.3	0.15
Number of QTL	100	10000
Sample Size	2000	800
SD of Dominance Coefficient ( $\delta$ )	0	1.0
SD of Epistatic Coefficient ( $\gamma$ )	0	0.7
Allele Frequency	Continuous Variable	

## Layout of Algorithm

(Based on Cokus et al., 2008)

TP: True positive; FP: False positive; FN: False negative;  
 $\alpha_k$ : True effect size;  $\hat{\alpha}_k$ : Estimated effect size;  $nqtl$ : Number of QTLs

## Results

Parameters	Power		True Positive Rate		MSE of Estimated Effect Sizes	
	Default Value	Alternative Value	Default Value	Alternative Value	Default Value	Alternative Value
Number of Generations	0.039	0.035*	0.708	0.763	0.043	0.030**
Proportion of Selected Males	0.039	0.039	0.692	0.478***	0.042	0.044
Effective Population Size	0.039	0.042*	0.706	0.437***	0.044	0.043
Narrow Sense Heritability	0.039	0.002***	0.694	0.610***	0.037	0.166***
Number of QTL	0.038	0.000***	0.683	0.514**	0.042	0.602***
Sample Size	0.040	0.008***	0.673	0.760*	0.037	0.107***
SD of Dominance Coefficient	0.039	0.041***	0.681	0.658	0.042	1.302***
SD of Epistatic Coefficient	0.040	0.112***	0.686	0.374***	0.044	2.768***

Significance Remarks:  
\* Weakly significant ( $1e-3 \geq p > 1e-4$ ); \*\* Significant ( $1e-4 \geq p > 1e-5$ ); \*\*\* Strongly Significant ( $p \leq 1e-5$ )

## Effect of Allele Frequency

Figure 1: The effect of allele frequency on (a) power and (b) mean squared error of estimated QTL effect size. Allele frequency do not have significant effect on True Positive Rate of GWAS.

## Conclusion

- Low selected male proportion and effective population size decrease true positive rate of GWAS.
- Large number of QTL and low heritability decrease the power and true positive rate of GWAS, while increase the MSE of estimated QTL effect sizes.
- With exception of dominance on true positive rate of GWAS, non-additive genetic components such as epistasis and dominance increase the power, but decrease the true positive rate and accuracy of estimated QTL effect sizes
